Abstract

The effect of the existence of tails on the propagation of scalar waves in curved space-time is considered via an analysis of flux integrals of the energy-stress-momentum tensor of the waves. The geometric optics approximation is formulated in terms of such flux integrals, and three examples are investigated in detail in order to determine the possible effects of wave tails. The approximation is valid for waves in Minkowski space-time (tail-free) and waves in Schwarzschild space-time (weak tails) but it is shown how the approximation can break down in a cosmological scenario due to destructive interference by strong tails. In this last situation, the waves do not radiate.

1 Introduction

It is well known that scalar, electromagnetic and gravitational fields in curved space-times do not, in general, propagate entirely along the null cone, but are accompanied by ‘tails’ which propagate in the interior of the null cone. Indeed tail-free propagation appears to be the exception rather than the rule [1, 2]. Wave tails manifest themselves in two ways; the ring down of a pulse of radiation from a bound source [3, 4], and partial back-scattering of the waves by the curvature [5, 6]. This latter effect may be represented graphically as follows (fig.1). A ray Γ entering a curved region Ω of space-time is partially transmitted (Γ_T) and partially reflected (Γ_R), or back-scattered, by the curvature. It has been argued that in astrophysical situations, where the curvature dies off rapidly away from the source, the existence of the necessarily weak tails has a negligible effect on the propagation of radiation; the reflected portion Γ_R diminishes rapidly far from the source [7]. On the other hand, in cosmology, strong local curvature causes back-scatter throughout the space-time, and tail effects may be considerable [8]. In fact it was shown in [5] that in the $k = -1$ Friedmann–Lemaître–Robertson–Walker (FLRW) space-time, the usual definition of reflection and transmission coefficients breaks down.

Fig. 1

A simple representation of back-scattering by curvature.

The aim of this paper is to discuss tail effects from the point of view of the energy-stress-momentum tensor of the (scalar, electromagnetic, gravitational) perturbation. The back-scattering effect is analysed by examining the flux of the energy-stress-momentum of the field across certain fundamental surfaces. Such scattering can be simply due to ‘potential barriers’ in the equations which exist in the absence of tails and are not curvature induced. Care is needed when seeking the source of reflection.

In particular, the geometric optics approximation for the field is considered. In the usual approaches [9, 10, 11], this involves writing the field as an asymptotic series in a small parameter ϵ (short wavelength or inverse high frequency) and analysing such high frequency modes. The results are well known; the light rays are null geodesics, and to zeroth order in ϵ , the field has an energy-stress-momentum tensor in the form of a null fluid. The approach taken here is to look for a geometric optics approximation to the full physical field, rather than its Fourier transform, at a finite distance from the source.

Three representative cases are analysed in detail: minimally coupled, massless scalar waves in Minkowski space-time, Schwarzschild space-time and the anti-Einstein static universe (the static $k = -1$ FLRW space-time). Scalar waves are used for simplicity, similar results would be obtained for electromagnetic and gravitational waves. The energy-stress-momentum of the field is most easily discussed in such static space-times, where one has a locally conserved 4-momentum for the field, leading to global conservation laws.

In §2, the fluxes of 4-momentum to be discussed are defined, and the geometric optics approximation is described in terms of these.

In §3, these fluxes are calculated for a general retarded solution of the scalar wave equation in Minkowski space-time, and the geometric optics approximation is obtained. The same is done in §4 for Schwarzschild space-time, and the results are compared and contrasted with those of §3.

The effect of strong local curvature is seen in §5, where scalar fields in the anti-Einstein universe are examined. A Green’s function approach is used, which shows transparently the rôle played by the tail term. It is argued that the strong tail completely back-scatters the radiation field, leaving only non-radiative field which does not escape to infinity.

The metric signature of $+2$ is used as are units in which $c = G = 1$, and lower case Latin indices run from 0 – 3.

2 Flux Integrals and the Geometric Optics Approximation

The Klein–Gordon equation is

$$\square\Psi - \xi R\Psi - m^2\Psi = 0, \quad (1)$$

where $\square = g^{ab}\nabla_a\nabla_b$ and R is the Ricci scalar of the space-time in question, ξ is a constant and m is the mass of the scalar field Ψ . In order that purely curvature induced effects are examined, only massless fields ($m = 0$) will be considered. In addition, for the three examples analysed in detail, $\xi R = 0$. Then the scalar field has a conserved symmetric energy-stress-momentum tensor,

$$T^{ab} = \nabla^a\Psi\nabla^b\Psi - \frac{1}{2}g^{ab}\nabla_c\Psi\nabla^c\Psi, \quad (2)$$

obeying $\nabla_a T^{ab} = 0$. In a static space-time, one may then construct a conserved 4-momentum for the field,

$$P^a = -T^{ab}\xi_b, \quad (3)$$

where ξ^a is the time-like Killing field of the space-time. Then P^a obeys $\nabla_a P^a = 0$.

Any static spherically symmetric space-time comes equipped with future null cones, $u = \text{constant}$, where u is retarded time, and surfaces of spherical symmetry, $r = \text{constant}$. Consider the 4-volume $\mathcal{V}$ bounded by the time-like surfaces $r = r_1$ and $r = r_2 > r_1$, and by the future null cones $u = u_1$ and $u = u_2 > u_1$. Take r_1 large enough so that $\mathcal{V}$ lies outside the source of Ψ (and outside the event horizon in the case of Schwarzschild). The flux of P^a across the surface $r = r_A$ ($A = 1, 2$) is

$${}^{(A)}F_T = \int_{u_1}^{u_2} \int_{\mathcal{S}_2} P^a r_{,a} \sqrt{-g} d_3x, \quad (4)$$

where the (A) indicates evaluation of the integral at $r = r_A$. The flux of P^a across the surface $u = u_A$ is

$${}^{(A)}F_R = \int_{r_1}^{r_2} \int_{\mathcal{S}_2} P^a u_{,a} \sqrt{-g} d_3x, \quad (5)$$

where the (A) indicates evaluation of the integral at $u = u_A$. The subscripts T and R indicate ‘transmitted’ and ‘reflected’ respectively. Integrating $\nabla_a P^a = 0$ over $\mathcal{V}$ and using the divergence theorem shows that

$$^{(1)}F_T + ^{(1)}F_R = ^{(2)}F_T + ^{(2)}F_R, \quad (6)$$

i.e. the flux of P^a entering $\mathcal{V}$ via the inner and lower surfaces equals the flux of P^a leaving $\mathcal{V}$ via the outer and upper surfaces. See [12] for more detail on such flux integrals in Minkowski space-time.

The generators of the future null cones have future-pointing tangent vector k^a , where

$$k_a = -u_{,a}, \quad (7)$$

and this will play the rôle of the ray vector for the field Ψ . A geometric optics energy-stress-momentum tensor ${}_{\text{GO}}T^{ab}$ is defined to be one for which for any volume $\mathcal{V}$ defined above,

- 1 ${}_{\text{GO}}F_T$ is independent of r , which will imply that ${}_{\text{GO}}F_T|_{\mathcal{J}^+}$ is finite, and
- 2 ${}_{\text{GO}}F_R = 0$.

(Clearly no left-hand superscript is needed in either case to indicate through which surface of $\mathcal{V}$ the flux is calculated.) The first condition says that Ψ contributes a non-zero finite amount of radiation at infinity (more precisely, at $\mathcal{J}^+$, where such is defined). The second condition indicates that there is no leakage of energy-momentum across the null cones $u = \text{constant}$; ${}_{\text{GO}}P^a$ propagates entirely along the null rays k^a . Such an energy-stress-momentum tensor ${}_{\text{GO}}T^{ab}$ satisfies Teitelboim’s criterion for ‘radiation at arbitrary distances’ [13]. A geometric optics energy-stress-momentum tensor could also be described as a pure radiation energy-stress-momentum tensor.

Condition (2) above is equivalent to ${}_{\text{GO}}P^a k_a = 0$, which in turn leads to ${}_{\text{GO}}P^a = F(x)k^a$, since ${}_{\text{GO}}P^a$ must be time-like or null. We continue the definition of a geometric optics energy-stress-momentum tensor as follows. The 4-momentum of Ψ as seen by an observer $\mathcal{O}$ with geodesic tangent 4-velocity v^a is

$$P^a(v) = -T^{ab}v_b. \quad (8)$$

Demanding that *every* observer measures this to be entirely in the outward null direction yields

$$T^{ab}v_b = G(x;v)k^a, \quad (9)$$

which along with the conditions above gives the usual form for a geometric optics energy-stress-momentum tensor,

$${}_{\text{GO}}T^{ab} = H(x)k^ak^b. \quad (10)$$

The geometric optics approximation is defined as follows [14].

The physical energy-stress-momentum tensor decomposes into two parts, ${}_{\text{RAD}}T^{ab}$ (radiative) and ${}_{\text{REM}}T^{ab}$ (remainder) which are separately conserved. ${}_{\text{RAD}}T^{ab}$ is a geometric optics energy-stress-momentum tensor as defined above, and includes the entire radiation field, in the sense that ${}_{\text{REM}}T^{ab}$ does not contribute any radiation at $\mathcal{J}^+$:

$${}_{\text{REM}}F_T|_{\mathcal{J}^+} = 0. \quad (11)$$

Demanding that ${}_{\text{RAD}}T^{ab}$ and ${}_{\text{REM}}T^{ab}$ be separately conserved is equivalent to saying that the energy-stress-momentum of the field splits into two parts which propagate independently of one another. Each piece will have associated with it a conservation equation of the form (6). Intuitively, ${}_{\text{RAD}}T^{ab}$ is the leading order term of T^{ab} in an expansion in inverse powers of some suitably defined distance parameter. Indeed, by hypothesis, when the geometric optics approximation holds, one has

$${}_{\text{RAD}}T^{ab} = H(x)k^ak^b, \quad (12)$$

which is conserved. This leads to the geodesic equation for k^a , and (on transforming to an affine parameter along the rays if necessary) to

$$DH + \theta H = 0, \quad (13)$$

where $D = k^a\nabla_a$ and $\theta = \nabla_a k^a$, which is an equation for the fall-off of H in terms of the affine parameter. This is a useful result, as it allows one to determine if a given energy-stress-momentum tensor includes radiation, simply by looking for the leading order behaviour implied by (13). If this strongest term is not present, the field does not radiate. This may be demonstrated as follows.

The line-element for static spherical symmetry may be written as

$$ds^2 = -f(r)du^2 - 2g(r)dudr + r^2d\omega^2, \quad (14)$$

where $d\omega^2$ is the line-element for the unit 2-sphere, f and g are positive outside horizons, and u is the retarded time. A convenient null tetrad is provided by $\{k^a, n^a, m^a, \bar{m}^a\}$, where

$$k_a = -u_{,a}, \quad \Rightarrow k^a = g^{-1}\delta_1^a, \quad (15)$$

$$n^a = \delta_0^a - \frac{1}{2}fg^{-1}\delta_1^a, \quad m^a = \frac{1}{\sqrt{2}r}(\delta_2^a + \frac{i}{\sin\theta}\delta_3^a). \quad (16)$$

The only non-zero inner products are $k^a n_a = -1$, $m^a \bar{m}_a = 1$, and $g_{ab} = -2k_{(a}n_{b)} + 2m_{(a}\bar{m}_{b)}$. Then $\theta = 2/(rg)$, and (13) may be integrated to obtain

$$H(x) = \frac{H_0}{r^2}, \quad (17)$$

where H_0 is independent of r . The time-like Killing field of (14) is

$$\xi^a = \frac{1}{2}fk^a + n^a, \quad (18)$$

and so from (3) and (12)

$${}_{\text{RAD}}P^a = \frac{H_0}{r^2}k^a. \quad (19)$$

From this, one obtains

$$F_T = \int_{u_1}^{u_2} du \int_{S_2} H_0 d\omega, \quad (20)$$

which is independent of r and will be non-zero in general, leading to a non-zero flux of radiation at $\mathcal{J}^+$. If $H(x)$ is any weaker than (17), i.e. if $H(x) = o(r^{-2})$, then F_T will be zero in the limit $r \rightarrow \infty$, indicating that there is no radiation at $\mathcal{J}^+$.

The fluxes defined above are calculated for three representative examples in the following sections, and it is shown how the presence of tails can influence the existence of the geometric optics approximation defined here.

3 Waves in Minkowski Space-Time

In Minkowski space-time, the general solution of $\square\Psi = 0$ which dies off as $r \rightarrow \infty$ and includes outgoing radiation can be obtained as follows. Expanding Ψ in spherical harmonics $Y_{l,m}$, one can write

$$\Psi = \sum_{l=0}^{\infty} \sum_{m=-l}^{+l} \Psi^{(l,m)} Y_{l,m}. \quad (21)$$

The equation obeyed by $\Psi^{(l,m)}$ is (with indices suppressed)

$$2\dot{\Psi}' - \Psi'' + \frac{2}{r}(\dot{\Psi} - \Psi') + \frac{l(l+1)}{r^2}\Psi = 0, \quad (22)$$

where a dot indicates partial differentiation with respect to u and a prime indicates partial differentiation with respect to r . For waves that die off as $r \rightarrow \infty$ one can write

$$\Psi = \sum_{n=1}^{\infty} \Psi_n^{(l,m)}(u) r^{-n}. \quad (23)$$

Filling out (22) and using static initial conditions one obtains

$$\begin{aligned} \Psi_n^{(l,m)} &= \frac{2^{l-n+1} l! (l+n-1)!}{(2l)! (n-1)! (l-n+1)!} \frac{d^{l-n+1} A_m(u)}{du^{l-n+1}}, \quad 1 \leq n \leq l+1, \\ \Psi_n^{(l,m)} &= 0, \quad n > l+1. \end{aligned} \quad (24)$$

The $A_m(u)$ are arbitrary functions of the null coordinate u . Thus the general solution obtained from (21), (23) and (24) obeys $\Psi = O(r^{-1})$, $\dot{\Psi} = O(r^{-1})$, $\Psi' = O(r^{-2})$ and $\delta\Psi = O(r^{-2})$ as $r \rightarrow \infty$, where $\delta = m^a \nabla_a$. Each of these relations may be differentiated with respect to r .

A straightforward calculation yields

$$\begin{aligned} T^{ab} &= \left(\frac{1}{2}\Psi' - \dot{\Psi}\right)^2 k^a k^b + (\Psi')^2 n^a n^b \\ &\quad + 2\bar{\delta}\Psi \left(\frac{1}{2}\Psi' - \dot{\Psi}\right) k^{(a} m^{b)} - 2\bar{\delta}\Psi \Psi' n^{(a} m^{b)} + (\bar{\delta}\Psi)^2 m^a m^b + \text{c.c.} \end{aligned} \quad (25)$$

The leading order term is easily identified;

$${}_{\text{RAD}}T^{ab} = \frac{H_0}{r^2} k^a k^b, \quad (26)$$

where

$$H_0(u, \theta, \phi) = \left(\sum_{l,m} \dot{\Psi}_1^{(l,m)} Y_{l,m} \right)^2. \quad (27)$$

This has the expected fall-off in terms of r , and is conserved. Thus so too is ${}_{\text{REM}}T^{ab} = T^{ab} - {}_{\text{RAD}}T^{ab}$. The existence of ${}_{\text{RAD}}T^{ab}$ in (26) above shows the validity of the geometric optics approximation as defined in §2 in this situation. One has ${}_{\text{RAD}}F_R = 0$ (no leakage of the radiation field across null cones) and ${}_{\text{REM}}F_T = O(r^{-2})$ (no contribution at $\mathcal{J}^+$ from the remainder field). It is worth pointing out that ${}_{\text{REM}}F_R \neq 0$, so that even in the absence of curvature, some of the field is reflected or back-scattered.

4 Waves in Schwarzschild Space-Time

Scalar waves in Schwarzschild space-time have tails. In this section, it is shown that the radiation field is unaffected by the existence of these tails, that is, the geometric optics approximation remains valid, in the sense of §2. The starting point is Bardeen and Press's careful analysis of radiation fields in the Schwarzschild background [6]. These authors obtained the general outgoing radiation solution of the scalar wave equation in the form

$$\Psi = \sum_{l,m} \Psi^{(l,m)}(u, r) Y_{l,m}, \quad (28)$$

where the coefficients (with indices suppressed) are of the form

$$\Psi = \Psi^{\text{I}} + \Psi^{\text{II}}, \quad (29)$$

with

$$\Psi^{\text{I}} = \sum_{n=1}^{l+1} f_n(u) r^{-n}, \quad (30)$$

$$\Psi^{\text{II}} = r^{-l-1} \sum_{k=1}^{\infty} a_k \left(\frac{2m}{r} \right)^k g_k(u, r). \quad (31)$$

The $g_k(u, r)$ are such that for each l , $\Psi^{\text{II}} = O(r^{-l-2})$, and $\Psi^{(l,m)}$ is uniformly convergent for all values of the retarded time u . As in the case of waves

in Minkowski space-time, the properties of Ψ^I and Ψ^{II} above lead to $\Psi = O(r^{-1})$, $\dot{\Psi} = O(r^{-1})$, $\Psi' = O(r^{-2})$ and $\delta\Psi = O(r^{-2})$ as $r \rightarrow \infty$, where $\delta = m^a \nabla_a$. Each of these relations may be differentiated with respect to r . The energy-stress-momentum tensor of the field Ψ is

$$\begin{aligned} T^{ab} = & \left(\frac{1}{2} \triangle \Psi' - \dot{\Psi}\right)^2 k^a k^b + (\Psi')^2 n^a n^b \\ & + 2\bar{\delta}\Psi \left(\frac{1}{2} \triangle \Psi' - \dot{\Psi}\right) k^{(a} m^{b)} - 2\bar{\delta}\Psi \Psi' n^{(a} m^{b)} + (\bar{\delta}\Psi)^2 m^a m^b + \text{c.c.} \end{aligned} \quad (32)$$

where $\triangle = 1 - 2m/r$ and m is the usual Schwarzschild mass parameter. Writing

$$\Psi = \Psi_0(u, \theta, \phi) r^{-1} + O(r^{-2}), \quad (33)$$

the leading order term in (32) is found to be

$${}_{\text{RAD}}T^{ab} = \frac{\dot{\Psi}_0^2}{r^2} k^a k^b, \quad (34)$$

which has the predicted fall-off and is conserved. The remainder term ${}_{\text{REM}}T^{ab} = T^{ab} - {}_{\text{RAD}}T^{ab}$ is then also conserved. Again as in Minkowski space-time, the geometric optics approximation is valid, and one has ${}_{\text{RAD}}F_R = 0$ (no leakage of the radiation field across null cones) and ${}_{\text{REM}}F_T = O(r^{-2})$ (no contribution at $\mathcal{J}^+$ from the remainder field). Thus there is no qualitative difference between the propagation of the *radiation* field in Minkowski and Schwarzschild space-time. Genuine back-scattering of other parts of the field was detected by Bardeen and Press[6], who showed that Ψ^{II} is constructed from terms which can be written in the form of ingoing waves on a flat background.

5 Waves in the anti-Einstein Universe

To illustrate the extreme properties that wave tails may have, consider the wave equation

$$(\square + \xi R)\Psi = j \quad (35)$$

on the static $k = -1$ FLRW space-time (the anti-Einstein universe), for which the line element is

$$ds^2 = -dt^2 + dr^2 + \sinh^2 r d\omega^2. \quad (36)$$

In (35), j is a source term and ξ is a constant.

The leading order term in the energy-stress-momentum tensor of Ψ should be the geometric optics term,

$${}_{\text{RAD}}T^{ab} = H(x)k^ak^b, \quad (37)$$

where $k^a = -g^{ab}u_{,b}$ is the outgoing null geodesic direction. Conservation of (37) and properties of k^a deduced from (36) show that

$$H(x) = \frac{H_0(u, \theta, \phi)}{\sinh^2 r}. \quad (38)$$

Thus in order that ${}_{\text{RAD}}T^{ab}$ may be constructed, one must have

$$\Psi(x) = \frac{\Psi_0(u, \theta, \phi)}{\sinh r} + o\left(\frac{1}{\sinh r}\right). \quad (39)$$

The object of the rest of this section is to show that this condition is *not* satisfied by quite general solutions Ψ of the minimally coupled wave equation.

Following the Green's function method of solution of DeWitt and Brehme [15], Hadamard's elementary solution of the homogeneous version of (35) is

$$G^{(1)}(x, x') = \frac{1}{4\pi}(\Sigma\Omega^{-1} + V\ln\Omega + W), \quad (40)$$

where Σ, V and W are two-point functions on space-time, free of singularities and Σ obeys

$$[\Sigma] \equiv \lim_{x \rightarrow x'} \Sigma(x, x') = 1. \quad (41)$$

Ω is the world function [16] of the space-time, given by, in the case of (36) above,

$$\Omega(x, x') \equiv -\frac{1}{2}s^2 = -\frac{1}{2}((t - t')^2 - \rho^2), \quad (42)$$

where

$$\cosh \rho = \cosh r \cosh r' - (\sin \theta \sin \theta' \cos(\phi - \phi') + \cos \theta \cos \theta') \sinh r \sinh r'. \quad (43)$$

See [17] for more details. The retarded Green's function is constructed from (40) and is given by

$$G^R(x, x') = \frac{1}{4\pi}(\Sigma\delta(\Omega) - V\theta(-\Omega))\theta(t - t'). \quad (44)$$

Then the retarded solution of (35) is

$$\Psi = \int G^R(x, x') j(x') d_4 x'. \quad (45)$$

For the space-time in question, one can show that

$$\Sigma = \frac{\rho}{\sinh \rho}, \quad (46)$$

and the Hadamard series expansion for V is

$$V = \frac{\rho}{\sinh \rho} \sum_{n=0}^{\infty} \frac{(1 - 6\xi)^{n+1}}{2^{n+1} n! (n+1)!} \Omega^n. \quad (47)$$

This is the tail term for the propagation of the field Ψ ; (44) shows that V contributes in the interior of the null cone, where $\Omega < 0$. Concentrating on two representative examples shows clearly the rôle played by V . For conformal coupling, $\xi = 1/6$ and $V = 0$. This is as expected, the propagation of Ψ on the conformally flat background of (36) is equivalent to propagation on Minkowski space-time. For minimal coupling, $\xi = 0$ and one can write

$$V = \frac{\rho}{\sinh \rho} s^{-1} J_1(s), \quad (48)$$

where J_1 is a Bessel function of the first kind.

To consider outgoing waves from a bound source, take $j(x)$ to be confined to a time-like world-line $C : x = z(\tau)$ where τ is proper time along C (see §5.6 of [1]). For a monopole source, which would dominate the radiation field, one may write

$$j(x') = \int_{-\infty}^{+\infty} q(\tau) \delta^{(4)}(x', z(\tau)) d\tau. \quad (49)$$

Splitting Ψ into the sharply propagated term and the tail term and integrating over x' yields $4\pi\Psi = f - g$, with

$$f(x) = \int_{-\infty}^{\infty} \Sigma\delta(\Omega)\theta(t - z^0(\tau))q(\tau) d\tau, \quad (50)$$

$$g(x) = \int_{-\infty}^{\infty} V\theta(-\Omega)\theta(t - z^0(\tau))q(\tau) d\tau. \quad (51)$$

The latter point in two point functions is now $x' = z(\tau)$. For convenience, and with no significant loss of generality, take C to be geodesic, which one can then assume to be $r = 0$. Then $z^a = \tau \delta_0^a$ and $\rho = r$. The delta function can be expanded as

$$\delta(\Omega) = \frac{\delta(\tau - u)}{r} + \frac{\delta(\tau - v)}{r}, \quad (52)$$

where $u \equiv t - r$ is retarded time and $v \equiv t + r$ is advanced time. One can then write

$$f(x) = \frac{q(u)}{\sinh r}, \quad (53)$$

and

$$g(x) = \frac{r}{\sinh r} \int_{-\infty}^u s^{-1} J_1(s) q(\tau) d\tau, \quad (54)$$

where now $s = [(t - \tau)^2 - r^2]^{1/2} \geq 0$. Eqn.(53) yields the solution for the conformally coupled equation.

The behaviour of $g(x)$ as $r \rightarrow \infty$ is determined as follows. Write $g(x) = I(x) \{r / \sinh r\}$. Integrating by parts once using $d(J_0(s)) = -s^{-1} J_1(s)(\tau - t) d\tau$ and asymptotic properties of J_0 [18] yields

$$I(x) = \frac{q(u)}{\sinh r} - I_1(x),$$

so that

$$\Psi(x) = \frac{1}{4\pi} \frac{r}{\sinh r} I_1, \quad (55)$$

where

$$I_1 = \int_{-\infty}^u J_0(s) \left\{ \frac{q'(\tau)}{(s^2 + r^2)^{1/2}} + \frac{q(\tau)}{s^2 + r^2} \right\} d\tau. \quad (56)$$

Next, assume that the source switched on at some finite time in the past, which we take to be $\tau = 0$. Then $q(\tau) = q'(\tau) = 0$ for $\tau < 0$, and $I_1 = I_2 + I_3$, with

$$I_2(x) = \int_0^u \frac{J_0(s)}{(s^2 + r^2)^{1/2}} q'(\tau) d\tau. \quad (57)$$

Using Schwarz's inequality, one may write

$$|I_2|^2 \leq M(u)I_4, \quad (58)$$

where

$$M(u) = \int_0^u (q'(\tau))^2 d\tau$$

is positive and

$$I_4(x) = \int_0^u \frac{J_0^2(s)}{s^2 + r^2} d\tau = \int_0^{s_1} \frac{sJ_0^2(s)}{(s^2 + r^2)^{3/2}} ds, \quad (59)$$

where $s_1 = (u^2 + 2ur)^{1/2}$. Integrating by parts using $sJ_0^2(s)ds = d\left\{\frac{s^2}{2}(J_0^2 + J_1^2)\right\}$ gives

$$I_4 = \frac{s_1^2}{2(s_1^2 + r^2)^{3/2}}(J_0^2(s_1) + J_1^2(s_1)) + \frac{3}{2} \int_0^{s_1} \frac{s^3}{(s^2 + r^2)^{5/2}} (J_0^2 + J_1^2) ds \quad (60)$$

In the limit $r \rightarrow \infty$, u finite (i.e. near $\mathcal{J}^+$), the first term in I_4 is

$$\frac{u^2 + 2ur}{2(u + r)^3} \left\{ \frac{2}{\pi} (u^2 + 2ur)^{-1/2} + O(r^{-1}) \right\} = \frac{(2u)^{1/2}}{\pi} r^{-5/2} + O(r^{-3}). \quad (61)$$

Using the upper bound $J_0^2 + J_1^2 \leq 3/2$, the second term in I_4 is dominated by

$$\frac{9}{4} \int_0^{s_1} \frac{s^3}{(s^2 + r^2)^{5/2}} ds = \frac{9}{4} u^2 r^{-3} + O(r^{-4}).$$

Thus one has the bound

$$|I_4| \leq \frac{(2u)^{1/2}}{\pi} r^{-5/2} + O(r^{-3}), \quad (62)$$

which gives $I_2 = O(r^{-5/4})$.

A bound for I_3 is obtained more easily. Again using Schwarz's inequality,

$$|I_3|^2 \leq N(u)I_5, \quad (63)$$

where

$$N(u) = \int_0^u q^2(\tau) d\tau$$

is positive and

$$I_5 = \int_0^{s_1} \frac{s}{(s^2 + r^2)^{5/2}} J_0^2(s) ds. \quad (64)$$

Using $|J_0| \leq 1$ gives

$$I_5 \leq \int_0^{s_1} \frac{s}{(s^2 + r^2)^{5/2}} ds = ur^{-4} + O(r^{-5}), \quad (65)$$

so that $I_3 = O(r^{-2})$.

The overall result is $I_1 = O(r^{-5/4})$, and so

$$\Psi(x) = \frac{1}{4\pi \sinh r} O(r^{-1/4}). \quad (66)$$

Thus Ψ falls off more rapidly than the rate necessary for the field to radiate. The separately conserved geometric optics energy-stress-momentum tensor ${}_{\text{RAD}}T^{ab}$ cannot be constructed, and in addition,

$$F_T|_{\mathcal{J}^+} = \lim_{r \rightarrow \infty} \int -T^{ab} \xi_a r_{,b} d_3 v = 0, \quad (67)$$

so that there is no radiation at $\mathcal{J}^+$. The interpretation of this result is clear. The tail term V , which is strongest on and near the null cone $\Omega = s = 0$, backscatters the *radiation field itself*, rather than just other non-radiative components of the field.

The situation for the solution $\Psi(x) = Q(u)/\sinh r$ of the tail-free conformally invariant equation (obtained from (53)) is more familiar. The appropriate energy-stress-momentum tensor is [19]

$$T^{ab} = \nabla^a \Psi \nabla^b \Psi - \frac{1}{4} g^{ab} \nabla_c \Psi \nabla^c \Psi - \frac{1}{2} \Psi \nabla^a \nabla^b \Psi - \frac{1}{4} \Psi^2 (R^{ab} - \frac{1}{6} R g^{ab}) \quad (68)$$

which for Ψ given above yields

$$\begin{aligned} T^{ab} = & \left\{ \frac{1}{\sinh^2 r} (\dot{Q}^2 - \frac{1}{2} Q \ddot{Q} + \frac{1}{2} Q \dot{Q}) + \frac{1}{2} \frac{e^{-r}}{\sinh^3 r} Q \dot{Q} \right\} k^a k^b \\ & + \frac{1}{2} \frac{Q^2}{\sinh^4 r} (k^{(a} n^{b)} + m^{(a} \bar{m}^{b)}). \end{aligned} \quad (69)$$

The leading order term is readily identified as

$${}_{\text{RAD}}T^{ab} = \frac{1}{\sinh^2 r}(\dot{Q}^2 - \frac{1}{2}Q\ddot{Q} + \frac{1}{2}Q\dot{Q})k^a k^b, \quad (70)$$

which displays the fall-off as $r \rightarrow \infty$ predicted in (38) above. As in §§3 and 4 above, one has ${}_{\text{RAD}}F_R = 0$ (no leakage of the radiation field across null cones) and $\lim_{r \rightarrow \infty} {}_{\text{REM}}F_T = 0$ (no contribution at $\mathcal{J}^+$ from the remainder field). The energy radiated through any $r = \text{constant}$ surface in the retarded time $u_2 - u_1$ is

$${}_{\text{RAD}}F_T = 4\pi \int_{u_1}^{u_2} (\dot{Q}^2 - \frac{1}{2}Q\ddot{Q} + \frac{1}{2}Q\dot{Q}) du, \quad (71)$$

which also gives the radiation rate at $\mathcal{J}^+$. The coefficient of k^a in

$${}_{\text{RAD}}P^a = \frac{1}{\sinh^2 r}(\dot{Q}^2 - \frac{1}{2}Q\ddot{Q} + \frac{1}{2}Q\dot{Q})k^a$$

should be positive to give a future pointing 4-momentum, which imposes restrictions on the source term $Q(\tau)$.

6 Discussion

The central technical result of §5 is eq.(66), the ‘too weak to radiate’ condition. This behaviour is generic, and does not depend on the assumptions about the source term $q(\tau)$ implicit throughout the calculation, nor indeed on the use of a monopole solution. This can be seen as follows.

The general solution for outgoing waves of the minimally coupled wave equation in the anti-Einstein universe can be written as [5]

$$\Psi(x) = \frac{1}{\sinh r} \int_{-\infty}^{\infty} e^{-i\omega t} \sum_{l,m} A_{l,m}(\omega) e^{ipr} F_{l,p}(z) Y_{l,m} d\omega, \quad (72)$$

where $p = \sqrt{\omega^2 - 1}$, the $F_{l,p}$ are (hypergeometric) polynomials

$$F_{l,p}(z) = \sum_{n=0}^l \binom{l+n}{l} \frac{(-l)_n}{(1-ip)_n} z^n, \quad (73)$$

$z = (1 - e^{2r})^{-1} \in (-\infty, 0)$ and the coefficients $A_{l,m}(\omega)$ arise from a time Fourier transform of a source term. Then using the Riemann-Lebesgue lemma and a minimal assumption on the behaviour of the source, one has, for each l, m [20],

$$A_{l,m}(\omega) = o(\omega), \quad \omega \rightarrow \pm\infty. \quad (74)$$

Thus to obtain the large r , finite u , behaviour of (72), one is lead to consider integrals of the form

$$I(r, u) = \int_{\Gamma} A(\omega) e^{-i\omega u} e^{iqr} d\omega, \quad (75)$$

where $q = \sqrt{\omega^2 - 1} - \omega$, $A(\omega) = o(\omega)$ as $\omega \rightarrow \pm\infty$ and apart from slight deformations, the contour Γ is of infinite extent, running from $Re(\omega) = -\infty$ to $Re(\omega) = +\infty$. Thus the integral is of the form examined in §9.5 of [21]; the results obtained are as follows. See the given reference for more details.

The relevant limit of (75) is $r \rightarrow +\infty$, u finite. Then one may assume (for u positive; u negative leads to similar results)

$$\epsilon \equiv \frac{u}{r} \in [0, \alpha), \quad (76)$$

where $\alpha \ll 1$. A *uniform* asymptotic expansion for (75) with ϵ in the given range is obtained in terms of Bessel functions of the first kind, with leading order behaviour

$$I(r; \epsilon) \sim b_0(\epsilon) I_0(r, \epsilon) + b_1(\epsilon) I_1(r, \epsilon), \quad (77)$$

where $b_n = O(1)$ as $\epsilon \rightarrow 0$, and

$$I_n = -2\pi i (2\gamma e^{-i\pi/2})^{\lambda+n} J_{\lambda+n}(\gamma r), \quad (78)$$

with $\gamma = (\epsilon^2 + \epsilon)^{1/2}$. The constant λ will be strictly positive (as a consequence of (74)), and for a source consisting of an oscillator at the origin, $\lambda = 1$ [21]. Since the result (77) is uniform in ϵ , one can substitute $\epsilon = u/r$ and obtain (using asymptotics of Bessel functions [18])

$$I(r, u) = O(r^{-1/4}). \quad (79)$$

This is the behaviour in the limiting case $\lambda = 0$; the more reasonable $\lambda = 1$ yields

$$I(r, u) = O(r^{-3/4}). \quad (80)$$

In any case, for very general sources, one finds

$$\Psi(x) = \frac{1}{\sinh r} O(r^{-1/4}), \quad (81)$$

which is eq.(66). The calculation given in §5 was preferred as it shows transparently the rôle played by the tail term.

An important question is whether or not the behaviour of scalar waves in the anti-Einstein universe is typical for waves in matter. Clearly, this will not be the case for electromagnetic waves in an FLRW universe, which have no tails. The interference of the tail with the radiation field arises from that part of the Green's function tail term V which is non-zero on the null cone. This is integrated out in the calculation preceding eq.(55), and cancels out the sharply propagated term. Consider the tail term $V_b^{a'}$ for the electromagnetic Green's function. A one-point expansion may be performed to give [15]

$$V_b^{a'}(x, x') = g_b^{a'} \sum_{n=0}^{\infty} V_{bb_1 \dots b_n}^c(x) \nabla^{b_1} \Omega \dots \nabla^{b_n} \Omega, \quad (82)$$

where $g_b^{a'}$ is the parallel propagator of the space-time. In general, $\nabla_a \Omega = O(s)$, and along the null cone, $\nabla_a \Omega(x, x')$ is the null geodesic direction at x , pointing from the source point x' to the field point x . The first term in (82) is

$$V_{ab} = R_{ab} - \frac{1}{6} R g_{ab}, \quad (83)$$

and the condition for this to be non-pure gauge is [22]

$$\nabla_{[c} R_{b]a} - \frac{1}{6} \nabla_{[c} R g_{b]a} \equiv \nabla^d C_{bcad} \neq 0. \quad (84)$$

In an almost-FLRW universe, this term can make small contributions to the tail along the null cone, as could higher order terms in (82), which can begin the annihilation of the radiation field which is total in §5. This may have

implications for the traditional use of the geometric optics approximation in cosmological observations [23], and warrants a more thorough investigation.

The author suggests that the geometric optics approximation discussed above provides a convenient way of determining if wave tails have a significant effect on the propagation of radiation in *any* space-time. The characterisation of a wave tail being strong - failure of the geometric optics approximation as formulated above - was motivated by analysing fluxes in space-times with nice global properties, but is stated in purely local terms and may be investigated in any space-time with asymptotic regions. The interpretation of the approximation is clear; there exists a part of the field (the radiation field) whose energy-stress-momentum tensor is ${}_{\text{RAD}}T^{ab}$, which detaches itself from the source and travels away to infinity at the speed of light, propagating independently of the rest of the field (${}_{\text{RAD}}T^{ab}$ is separately conserved). As viewed by any observer, the radiation field is in the outward null direction, and includes all of the radiation emitted by the source of the field. The strength of wave tails for Maxwell's equations is currently being investigated in these terms in asymptotically flat space-times, wherein it is fully expected that the geometric optics approximation is valid, and hence the tails are insignificant [7].

Finally, it is tempting to consider an extension of this discussion to the gravitational field. This has already been carried out in the case of the linearized theory[24]; it would be interesting to see the relationship with the quasi-localisation of Bondi–Sachs mass loss [25].

Acknowledgements

I am indebted to Chris Luke for many useful conversations and for introducing me to asymptotics.
